(54) Title: METHOD AND APPARATUS FOR REDUCING MITRAL REGURGITATION

(57) Abstract: A method for reducing mitral regurgitation includes deploying deforming matter (157) into a selected one of a mitral valve annulus adjacent a posterior leaflet and tissue adjacent the mitral valve annulus proximate the posterior leaflet, to cause a conformational change in the annulus, and thereby a conformational change in the posterior leaflet, to increase mitral valve leaflet coaptation.

AND APPARATUS TO IMPROVE MITRAL VALVE FUNCTION  
(Attorney's Docket No. VIA-31 PROV).

10 The aforementioned five (5) patent applications  
are hereby incorporated herein by reference.

#### Field Of The Invention

15 This invention relates to surgical methods and  
apparatus in general, and more particularly to surgical  
methods and apparatus for improving mitral valve  
function.

#### Background Of The Invention

20 Mitral valve repair is the procedure of choice to  
correct mitral regurgitation of all etiologies. With  
the use of current surgical techniques, between 70% and  
95% of regurgitant mitral valves can be repaired. The

VIA-30

- 3 -

advantages of mitral valve repair over mitral valve replacement are well documented. These include better preservation of cardiac function and reduced risk of anticoagulant-related hemorrhage, thromboembolism and endocarditis.

In current practice, mitral valve surgery requires an extremely invasive approach that includes a chest wall incision, cardiopulmonary bypass, cardiac and pulmonary arrest, and an incision on the heart itself to gain access to the mitral valve. Such a procedure is associated with high morbidity and mortality. Due to the risks associated with this procedure, many of the sickest patients are denied the potential benefits of surgical correction of mitral regurgitation. In addition, patients with moderate, symptomatic mitral regurgitation are denied early intervention and undergo surgical correction only after the development of cardiac dysfunction.

Mitral regurgitation is a common occurrence in patients with heart failure and a source of important morbidity and mortality in these patients. Mitral regurgitation in patients with heart failure is caused

- 4 -

by changes in the geometric configurations of the left  
ventricle, papillary muscles and mitral annulus. These  
geometric alterations result in incomplete coaptation  
of the mitral leaflets during systole. In this  
5 situation, mitral regurgitation is corrected by  
plicating the mitral valve annulus, either by sutures  
alone or by sutures in combination with a support ring,  
so as to reduce the circumference of the distended  
annulus and restore the original geometry of the mitral  
10 valve annulus.

More particularly, current surgical practice for  
mitral valve repair generally requires that the mitral  
valve annulus be reduced in radius by surgically  
opening the left atrium and then fixing sutures, or  
15 more commonly sutures in combination with a support  
ring, to the internal surface of the annulus; this  
structure is used to pull the annulus back into a  
smaller radius, thereby reducing mitral regurgitation  
by improving leaflet coaptation.

20 This method of mitral valve repair, generally  
termed "annuloplasty", effectively reduces mitral  
regurgitation in heart failure patients. This, in

- 5 -

turn, reduces symptoms of heart failure, improves quality of life and increases longevity.

Unfortunately, however, the invasive nature of mitral valve surgery and the attendant risks render most heart failure patients poor surgical candidates. Thus, a less invasive means to increase leaflet coaptation and thereby reduce mitral regurgitation in heart failure patients would make this therapy available to a much greater percentage of patients.

10 Mitral regurgitation also occurs in approximately 20% of patients suffering acute myocardial infarction. In addition, mitral regurgitation is the primary cause of cardiogenic shock in approximately 10% of patients who develop severe hemodynamic instability in the setting of acute myocardial infarction. Patients with 15 mitral regurgitation and cardiogenic shock have about a 50% hospital mortality. Elimination of mitral regurgitation in these patients would be of significant benefit. Unfortunately, however, patients with acute 20 mitral regurgitation complicating acute myocardial infarction are particularly high-risk surgical candidates, and are therefore not good candidates for a

- 6 -

traditional annuloplasty procedure. Thus, a minimally  
invasive means to effect a temporary reduction or  
elimination of mitral regurgitation in these critically  
ill patients would afford them the time to recover from  
5 the myocardial infarction or other acute life-  
threatening events and make them better candidates for  
medical, interventional or surgical therapy.

#### Summary Of The Invention

10 As a result, one object of the present invention  
is to provide an improved method and apparatus for  
reducing mitral regurgitation.

Another object of the present invention is to  
provide a method and apparatus for reducing mitral  
15 regurgitation which is minimally invasive.

Another object of the present invention is to  
provide a method and apparatus for reducing mitral  
regurgitation which can be deployed either permanently  
(e.g., for patients suffering from heart failure) or  
20 temporarily (e.g., for patients suffering from mitral  
regurgitation with acute myocardial infarction).

- 7 -

These and other objects are addressed by the present invention, which comprises an improved method and apparatus for reducing mitral regurgitation.

5 In one form of the invention, there is provided a method for reducing mitral regurgitation comprising: inserting apparatus into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the apparatus being adapted to straighten the natural curvature of at least a portion of the  
10 coronary sinus in the vicinity of the posterior leaflet of the mitral valve, whereby to move the posterior annulus anteriorly and thereby improve leaflet coaptation.

15 In another form of the invention, there is provided a method for reducing mitral regurgitation comprising: inserting apparatus into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the apparatus being adapted to move at least a portion of the coronary sinus in the  
20 vicinity of the posterior leaflet of the mitral valve anteriorly, whereby to move the posterior annulus anteriorly and thereby improve leaflet coaptation.

VIA-30

- 8 -

In another form of the invention, there is provided a method for reducing mitral regurgitation comprising: inserting apparatus into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the apparatus being adapted to reduce the degree of natural curvature of at least a portion of the coronary sinus in the vicinity of the posterior leaflet of the mitral valve, whereby to move the posterior annulus anteriorly and thereby improve leaflet coaptation.

In another form of the invention, there is provided a method for reducing mitral regurgitation comprising: inserting apparatus into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the apparatus being adapted to increase the natural radius of curvature of at least a portion of the coronary sinus in the vicinity of the posterior leaflet of the mitral valve, whereby to move the posterior annulus anteriorly and thereby improve leaflet coaptation.

In another form of the invention, there is provided a method for reducing mitral regurgitation

- 9 -

comprising: inserting apparatus into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the apparatus having a distal end, a proximal end and an intermediate portion, the apparatus being configured so that when the apparatus is positioned in the coronary sinus in the vicinity of the posterior leaflet of the mitral valve, the distal and proximal ends will apply a posteriorly-directed force to the walls of the coronary sinus and the intermediate portion will apply an anteriorly-directed force to the walls of the coronary sinus, whereby to move the posterior annulus anteriorly and thereby improve leaflet coaptation.

In another form of the invention, there is provided a method for reducing mitral regurgitation comprising: inserting a substantially straight elongated body into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the length of the substantially straight elongated body being sized relative to the natural curvature of the coronary sinus in the vicinity of the posterior leaflet of the mitral valve so that when the

VIA-30

- 10 -

substantially straight elongated body is positioned in the coronary sinus, it will cause at least a portion of the coronary sinus to assume a substantially straight configuration adjacent to the posterior leaflet of the mitral valve, whereby to increase the radius of curvature of the mitral annulus and thereby improve leaflet coaptation.

In another form of the invention, there is provided a method for reducing mitral regurgitation comprising: inserting a substantially rigid elongated body into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the substantially rigid elongated body being configured relative to the natural curvature of the coronary sinus in the vicinity of the posterior leaflet of the mitral valve so that when the substantially rigid elongated body is positioned in the coronary sinus, it will cause at least a portion of the coronary sinus to assume a different configuration adjacent to the posterior leaflet of the mitral valve, whereby to move the posterior annulus anteriorly and thereby improve leaflet coaptation.

VIA-30

- 11 -

In another form of the invention, there is provided a method for reducing mitral regurgitation comprising: inserting a straight, substantially rigid elongated body into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the length of the straight, substantially rigid elongated body being sized relative to the natural curvature of the coronary sinus in the vicinity of the posterior leaflet of the mitral valve so that when the straight, substantially rigid elongated body is positioned in the coronary sinus, it will cause at least a portion of the coronary sinus to assume a substantially straight configuration adjacent to the posterior leaflet of the mitral valve, whereby to increase the radius of curvature of the mitral annulus and thereby improve leaflet coaptation.

In another form of the invention, there is provided an apparatus for reducing mitral regurgitation comprising: a body having a distal end, a proximal end and an intermediate portion, the body being configured so that when the body is positioned in the coronary sinus in the vicinity of the posterior leaflet of the

- 12 -

mitral valve, the distal and proximal ends will apply a posteriorly-directed force to the walls of the coronary sinus, and the intermediate portion will apply an anteriorly-directed force to the walls of the coronary sinus, whereby to move the posterior annulus of the mitral valve anteriorly and thereby improve leaflet coaptation.

In another form of the invention, there is provided an apparatus for reducing mitral regurgitation comprising: a substantially straight elongated body adapted to be inserted into the coronary sinus of a patient in the vicinity of the posterior leaflet of the mitral valve, the length of the substantially straight elongated body being sized relative to the natural curvature of the coronary sinus in the vicinity of the posterior leaflet of the mitral valve so that when the substantially straight elongated body is positioned in the coronary sinus, it will cause at least a portion of the coronary sinus to assume a substantially straight configuration adjacent to the posterior leaflet of the mitral valve, whereby to increase the radius of

- 13 -

curvature of the mitral annulus, moving it anteriorly,  
and thereby improve leaflet coaptation.

In another form of the invention, there is  
provided an apparatus for reducing mitral regurgitation  
5 comprising: a substantially rigid elongated body  
adapted to be inserted into the coronary sinus of a  
patient in the vicinity of the posterior leaflet of the  
mitral valve, the length of the straight, substantially  
rigid elongated body being sized relative to the  
10 natural curvature of the coronary sinus in the vicinity  
of the posterior leaflet of the mitral valve so that  
when the substantially rigid elongated body is  
positioned in the coronary sinus, it will cause at  
least a portion of the coronary sinus to assume a  
15 different configuration adjacent to the posterior  
leaflet of the mitral valve, whereby to move the  
posterior annulus anteriorly and thereby improve  
leaflet coaptation.

In another form of the invention, there is  
20 provided an apparatus for reducing mitral regurgitation  
comprising: a straight, substantially rigid elongated  
body adapted to be inserted into the coronary sinus of

VIA-30

- 14 -

a patient in the vicinity of the posterior leaflet of the mitral valve, the length of the straight, substantially rigid elongated body being sized relative to the natural curvature of the coronary sinus in the vicinity of the posterior leaflet of the mitral valve so that when the straight, substantially rigid elongated body is positioned in the coronary sinus, it will cause at least a portion of the coronary sinus to assume a substantially straight configuration adjacent to the posterior leaflet of the mitral valve, whereby to increase the radius of curvature of the mitral annulus, moving it anteriorly, and thereby improve leaflet coaptation.

In still another form of the invention, there is provided a method for reducing mitral regurgitation, the method comprising deploying matter into a selected one of (i) a mitral valve annulus and (ii) tissue adjacent the mitral valve annulus, to cause conformational change in the annulus, and thereby a posterior leaflet, to increase mitral valve leaflet coaption.

VIA-30

- 15 -

In accordance with a further feature of the invention, there is provided an assembly for reducing mitral regurgitation, the assembly including a delivery catheter adapted for insertion into a coronary sinus, a  
5 needle for movement through the delivery catheter and adapted to penetrate the coronary sinus and enter tissue between the coronary sinus and a mitral valve annulus adjacent a posterior leaflet, and adapted to enter the mitral valve annulus, and deforming matter  
10 adapted to be carried by the needle and deployed in at least one of the tissue and the mitral valve annulus.

Significantly, the present invention may be practiced in a minimally invasive manner, either permanently or temporarily, so as to reduce mitral  
15 regurgitation.

#### Brief Description Of The Drawings

These and other objects and features of the present invention will be more fully disclosed or  
20 rendered obvious by the following detailed description of the preferred embodiments of the invention, which is to be considered together with the accompanying

VIA-30

- 16 -

drawings wherein like numbers refer to like parts and further wherein:

10 Detailed Description Of The Preferred Embodiments

The coronary sinus is the largest vein in the human heart. During a large portion of its course in the atrioventricular groove, the coronary sinus typically extends adjacent to the left atrium of the heart for a distance of approximately 5 to 10 centimeters. Significantly, for a portion of its length, e.g., typically approximately 7-9 cm, the coronary sinus extends substantially adjacent to the posterior perimeter of the mitral annulus. The present invention takes advantage of this consistent anatomic relationship. More particularly, by deploying novel apparatus in the coronary sinus, adjacent to the

- 20 -

posterior leaflet of the mitral valve, the natural curvature of the coronary sinus may be modified in the vicinity of the posterior leaflet of the mitral valve, whereby to move the posterior annulus anteriorly so as to improve leaflet coaptation and, as a result, reduce mitral regurgitation.

In one preferred embodiment of the invention, the novel apparatus comprises a straight, substantially rigid elongated body, the length of the straight, substantially rigid elongated body being sized so that when the straight, substantially rigid body is positioned in the coronary sinus in the vicinity of the posterior leaflet of the mitral valve, the straight, substantially rigid elongated body will cause at least a portion of the coronary sinus to assume a substantially straight configuration adjacent to the posterior leaflet of the mitral valve, whereby to move the posterior annulus anteriorly and thereby improve leaflet coaptation.

And in one preferred embodiment of the invention, access to the coronary sinus is gained percutaneously, e.g., the straight, substantially rigid elongated body

VIA-30

- 21 -

is introduced into the patient's vascular system via the jugular vein or via the left subclavian vein, passed down the superior vena cava, passed through the right atrium and then passed into the coronary sinus, where it is deployed. Alternatively, the straight, substantially rigid elongated body may be introduced into the coronary sinus through a small incision in the heart, or through some other incision into the patient's vascular system.

And in one preferred embodiment of the invention, the straight, substantially rigid elongated body is guided into position by (i) passing it through a pre-positioned catheter, or (ii) passing it over a pre-positioned guidewire, or (iii) passing it guide-free (e.g., on the end of a steerable delivery tool) to the surgical site.

Once deployed, the novel apparatus may be left in position permanently (e.g., in the case of patients suffering from mitral regurgitation associated with heart failure) or the novel apparatus may be left in position only temporarily (e.g., in the case of

- 22 -

patients suffering from mitral regurgitation associated with acute myocardial infarction).

Visualization of the procedure may be obtained by fluoroscopy, echocardiography, intravascular  
5 ultrasound, angioscopy, real-time magnetic resonance imaging, etc. The efficacy of the procedure may be determined through echocardiography, although other imaging modalities may also be suitable.

Looking now at Figs. 1 and 2, there are shown  
10 aspects of the cardiovascular system 3 of a patient. More particularly, cardiovascular system 3 generally comprises the heart 6, the superior vena cava 9 (Fig. 1), the right subclavian vein 12, the left subclavian vein 15, the jugular vein 18, and the inferior vena  
15 cava 21. Superior vena cava 9 and inferior vena cava 21 communicate with the heart's right atrium 24 (Figs. 1 and 2). The coronary ostium 27 leads to coronary sinus 30. At the far end 31 (Fig. 2) of coronary sinus 30, the vascular structure turns into the vertically-  
20 descending anterior interventricular vein ("AIV") 32 (Fig. 1). For purposes of the present invention, it can generally be convenient to consider the term

VIA-30

- 23 -

"coronary sinus" to mean the vascular structure extending between coronary ostium 27 and AIV 32.

As seen in Fig. 2, between coronary ostium 27 and AIV 32, coronary sinus 30 generally extends

5 substantially adjacent to the posterior perimeter of the annulus 33 of the mitral valve 36. Mitral valve 36 comprises a posterior leaflet 39 and an anterior leaflet 42. In the case of a regurgitant mitral valve, posterior leaflet 39 and anterior leaflet 42 will

10 generally fail to properly coapt at systole, thereby leaving an intervening gap 45 which will permit regurgitation.

Looking next at Fig. 3, there is shown a system 100 which comprises one preferred embodiment of the

15 present invention. More particularly, system 100 generally comprises a guidewire 103, a delivery catheter 106 and a push rod 109.

Guidewire 103 comprises a flexible body 112 having a distal end 115 and a proximal end 118. The distal

20 end 115 of guidewire 103 preferably includes a spring tip 121 for allowing the distal end of guidewire 106 to atraumatically traverse vascular structures, i.e.,

VIA-30

- 24 -

while the guidewire is being passed through the vascular system of a patient.

Delivery catheter 106 comprises a flexible body 124 having a distal end 127 and a proximal end 130, preferably with an adjustable valve 133 attached. A central lumen 136 extends from distal end 127 to proximal end 130. In some circumstances it may be desirable to provide a securing mechanism for securing the distal end of the delivery catheter within a vascular structure. By way of example but not limitation, a balloon 139 may be positioned about the exterior of flexible body 124, just proximal to distal end 127, with an inflation lumen 142 extending between balloon 139 and an inflation fitting 145.

Push rod 109 comprises a flexible body 148 having a distal end 151 and a proximal end 154. A straight, substantially rigid elongated body 157, which may have a variety of different lengths, is formed on flexible body 148, proximal to distal end 151. A removable proximal stiffener or handle 160 may be placed between straight, substantially rigid elongated body 157 and proximal end 154.

VIA-30

- 25 -

System 100 may be used as follows to reduce mitral regurgitation.

First, distal end 115 of guidewire 103 is passed down the jugular vein 18 (or the left subclavian vein 15) of a patient, down superior vena cava 9, through right atrium 24 of the heart, and then into coronary sinus 30. See Fig. 4. It will be appreciated that as flexible guidewire 103 is passed down coronary sinus 30, the guidewire will tend to assume the natural curved shape of the coronary sinus, due to the flexible nature of the guidewire. The guidewire's atraumatic spring tip 121 will help ensure minimal damage to vascular structures as guidewire 103 is maneuvered into position.

Next, distal end 127 of delivery catheter 106 is placed over proximal end 118 of guidewire 103 and passed down the guidewire until the distal end of the delivery catheter is positioned in coronary sinus 30. See Fig. 5. Again, it will be appreciated that as the flexible delivery catheter 106 passes down the coronary sinus, the delivery catheter will tend to assume the

VIA-30

- 26 -

natural curved shape of the coronary sinus, due to the flexible nature of the delivery catheter.

Once delivery catheter 106 has been positioned within the coronary sinus, guidewire 103 is removed.

5 See Fig. 6. Either before or after guidewire 103 is removed, balloon 139 may be inflated so as to secure distal end 127 of delivery catheter 106 in position within coronary sinus 30.

10 Next, push rod 109 is passed down the central lumen 136 of delivery catheter 106. As the push rod's straight, substantially rigid elongated body 157 is passed down central lumen 136 of delivery catheter 106, it will force the delivery catheter to assume a straight configuration at the point where the straight, substantially rigid elongated body 157 currently  
15 resides. As push rod 109 is pushed down delivery catheter 106, balloon 139 will hold the distal end of the delivery catheter in position within coronary sinus 30.

20 Push rod 109 is pushed down delivery catheter 106, utilizing removable proximal stiffener 160 as needed, until the straight, substantially rigid elongated body

VIA-30

- 27 -

157 is located adjacent to the posterior annulus of  
mitral valve 36. See Fig. 7. As this occurs, the  
presence of the straight, substantially rigid elongated  
body 157 in delivery catheter 106 will cause at least a  
5 portion of coronary sinus 30 to assume a substantially  
straight configuration at this point, so that the  
posterior annulus of mitral valve 36 is forced  
anteriorly. This will cause the mitral valve's  
posterior leaflet 39 to also move anteriorly so as to  
10 improve mitral valve leaflet coaptation and thereby  
reduce (or completely eliminate) mitral valve  
regurgitation. In this respect it should be  
appreciated that the posterior annulus may be shifted  
anteriorly so as to achieve, or to attempt to achieve  
15 to the extent anatomically possible, leaflet-to-leaflet  
engagement or leaflet-to-annulus engagement (e.g.,  
where a leaflet may be tethered due to left ventricular  
distortion). Both of these types of engagement, or  
targeted engagement, are intended to be encompassed by  
20 the terms "improved leaflet coaptation" and/or  
"increased leaflet coaptation" and the like. Using  
standard visualization means (e.g. echocardiography or

VIA-30

- 28 -

fluoroscopy), the exact position of the straight, substantially rigid elongated body 157 is adjusted so as to reduce (or completely eliminate) regurgitation in mitral valve 36.

5           In this respect it should be appreciated that the straight, substantially rigid elongated body 157 is preferably sized to be somewhat less than the length of the coronary sinus between coronary ostium 27 and AIV 32. However, in some circumstances it may be desirable  
10       to size the straight, substantially rigid elongated body 157 so that it will extend out of the coronary sinus and into the right atrium.

          Furthermore, it should also be appreciated that the system provides a degree of tactile feedback to the  
15       user during deployment. More particularly, substantial resistance will typically be encountered as the straight, substantially rigid elongated body 157 is pushed out of right atrium 24 and into coronary sinus 30; then resistance will typically drop as body 157 is  
20       moved through the coronary sinus; and then resistance will typically increase significantly again as the distal tip of body 157 comes to the far end 31 of the

VIA-30

- 29 -

coronary sinus. Thus, there is a sort of tactile  
"sweet spot" when the straight, substantially rigid  
elongated body 157 is located in the coronary sinus  
between coronary ostium 27 and AIV 32, and this tactile  
5 "sweet spot" can be helpful to the user in positioning  
the straight, substantially rigid elongated body 157 in  
coronary sinus 30.

At this point the straight, substantially rigid  
elongated body 157 is locked in position, e.g., by  
10 closing adjustable valve 133, and balloon 139 may be  
deflated.

System 100 is left in this position until it is no  
longer needed. In some cases this may mean that system  
100 is left in position for a period of a few hours,  
15 days or weeks; in other cases system 100 may be  
substantially permanent. If and when system 100 is to  
be removed, push rod 109 is removed from delivery  
catheter 106, and then delivery catheter 106 is removed  
from the patient.

20 Thus it will be seen that with the present  
invention, the straight, substantially rigid elongated  
body 157 is essentially force-fit into the normally

VIA-30

- 30 -

curved portion of the coronary sinus adjacent to the mitral valve's posterior leaflet. By properly sizing the length of the straight, substantially rigid elongated body 157 relative to the natural curvature of the patient's anatomy, and by properly positioning the straight, substantially rigid elongated body 157 in the patient's coronary sinus, the straight, substantially rigid elongated body will cause at least a portion of the coronary sinus to assume a substantially straight configuration adjacent to the posterior leaflet of the mitral valve. This action will in turn drive the posterior annulus of the mitral valve anteriorly, so as to improve leaflet coaptation and thereby reduce mitral regurgitation. Thus, by inserting the straight, substantially rigid elongated body 157 into the coronary sinus adjacent to the posterior leaflet of the mitral valve, the annulus of the mitral valve is effectively manipulated so that it will assume an increased radius of curvature.

It has also been found that by inserting the straight, substantially rigid elongated body into the coronary sinus adjacent to the posterior leaflet of the

VIA-30

- 31 -

mitral valve, the left ventricle may also be remodeled so as to help alleviate congestive heart failure.

It is significant to note that with the present invention, the distal and proximal ends of straight, substantially rigid elongated body 157 apply a posteriorly-directed force on the walls of coronary sinus 30 (e.g., as shown with arrows P in Fig. 7) while the intermediate portion of straight, substantially rigid elongated body 157 applies an anteriorly-directed force on the walls of coronary sinus 30 (e.g., as shown with arrows A in Fig. 7).

In some cases the proximal end 130 of delivery catheter 106 may be fixed to the patient's outer skin using standard patient care methods such as adhesive tape, pursestring sutures, skin staples, etc. In other cases proximal end 130 of delivery catheter 106 may include a sewing cuff whereby the delivery catheter may be secured to the patient's tissue by suturing. See, for example, Fig. 8, where a sewing cuff 166 is shown attached to the proximal end 130 of delivery catheter 106. If desired, an element 169 may be provided proximal to adjustable valve 133, whereby flexible push

VIA-30

- 32 -

rod 109 may be made fast to delivery catheter 106. By way of example, element 169 may comprise a crimpable element to secure flexible push rod 109 to delivery catheter 106, which is in turn secured to the patient.

5           If desired, the proximal end of the assembly may be embedded under the skin of the patient, e.g., in the case of a permanent implant.

          As noted above, it can be helpful to anchor the distal end of delivery catheter 106 in position within  
10   the coronary sinus prior to pushing push rod 109 into the delivery catheter. Such an arrangement will keep the delivery catheter in place as the push rod makes the turn within the right atrium and enters the coronary sinus. In the absence of such anchoring, the  
15   push rod may drive the delivery catheter down the inferior vena cava 21. By securing the distal end of delivery catheter 106 to the walls of coronary sinus 30, the delivery catheter can be stabilized against  
20   diversion down the inferior vena cava 21 when the straight, substantially rigid elongate body 157 encounters initial resistance to making the turn into the coronary sinus.

VIA-30

- 33 -

The balloon 139 is one way of accomplishing such anchoring. However, it is also possible to utilize other types of securing mechanisms to anchor the distal end 127 of delivery catheter 106 in position within coronary sinus 30, e.g., spring clips, ribs, etc.

Alternatively, and looking next at Fig. 9, the distal end 151 of push rod 109 may itself be provided with a distal anchor, e.g., such as the distal anchor 172 shown in Fig. 9.

It is also possible to prevent diversion of delivery catheter 106 down inferior vena cava 21 without anchoring the distal end of delivery catheter 106 or flexible push rod 109 to the walls of the coronary sinus. More particularly, and looking now at Fig. 9A, there is shown a support catheter 173 which is formed out of a more rigid material than delivery catheter 106. Support catheter 173 is constructed so that its distal end 174 can be positioned in coronary ostium 27 and then its sidewall 174A can support delivery catheter 106 adjacent to inferior vena cava 21 when push rod 109 is passed down delivery catheter 106, whereby to prevent delivery catheter 106 from diverting

- 34 -

down inferior vena cava 106. Fig. 9A also shows an introducer catheter 174B at the entrance to jugular vein 18.

Looking next at Fig. 9B, there is shown a push rod 112A which comprises an alternative form of push rod. Push rod 112A comprises a flexible body 148A having a distal end 151A and a proximal end 154A. Preferably flexible body 148A is formed out of a superelastic shape memory alloy such as Nitinol. A straight, substantially rigid member 157A is formed on body 148A, proximal to distal end 151A. Substantially rigid member 157A can have a variety of different lengths so as to accommodate different patient anatomies. A tube 158A is positioned concentrically over flexible body 148A and extends for at least part of the distance between substantially rigid member 157A and a locking collar 159A secured to proximal end 154A of flexible body 148A. Tube 158A serves as a stiffener or reinforcer for flexible body 148A, whereby flexible body 148A can have the flexibility required (particularly at its distal end) to traverse tortuous vascular passages, yet have the column strength

VIA-30

- 35 -

(particularly at its proximal end) to advance flexible body 148A by pushing. In addition, tube 158A can be sized so as to have a diameter just slightly smaller than the internal diameter of delivery catheter 106, whereby to further support flexible body 148A. In one preferred form of the invention, tube 158A preferably comprises a PEEK tube.

Looking next at Fig. 9C, flexible body 148A can also be necked down, e.g., as shown at 220, so as to further increase the flexibility of flexible body 148A distal to tube 158A.

Flexible push rod 112A is preferably a device with a series of changes in stiffness and flexibility that allows the device to be bending flexible and column strength sufficient to pass through an arduous path, such as the vascular system, yet have specific areas of stiffness to reduce mitral valve regurgitation by pushing the posterior annulus anteriorly and thus closing the gap between the anterior and posterior leaflets of the mitral valve. One preferred embodiment of this device is a single rod of superelastic material, such as Nitinol, that has a plurality of

- 36 -

changes in diameter that allows for bending flexibility. The largest diameter section has a bending stiffness sufficient to push the posterior annulus anteriorly. The longest portions of the rod have many serrations that provide bending flexibility along with column strength.

Alternatively, and looking next at Fig. 9D, it is also possible to provide additional flexibility to flexible body 148A by severing the flexible body along its length and then connecting the two severed portions with a flexible tube or wire, e.g., such as is shown at 225.

In addition to the foregoing, in an alternative embodiment as shown in Figure 9E, it is also possible to use guiding catheter 162, preferably with a pre-formed tip 164, which could be advanced over guidewire 103 whereby performed tip 164 of guiding catheter 162 would engage the opening of the coronary sinus vessel. This tip 164 is sufficiently flexible to execute extreme bends, and may be of reduced diameter. Upon successful engagement and advancement of the guiding catheter tip 164 a short distance into the coronary

- 37 -

sinus, guidewire 103 is removed. Then delivery catheter 106 is advanced toward and into the coronary sinus through the center lumen 165 of guiding catheter 162. Then, push rod 109 would be advanced within center lumen 136 of the delivery catheter into the coronary sinus and into position as described herein.

It is also envisioned that the structure of guiding catheter 162 would be added onto delivery catheter 106 to enable the placement of the distal tip of delivery catheter 106 into the coronary sinus and enable the delivery of push rod 109, thereby combining the function of the two catheters into one catheter with only the center lumen 136 within the combined guide and delivery catheter 106 and a closed distal tip (i.e. single lumen catheter).

As noted above, as push rod 109 or 112A is advanced to the region adjacent to the posterior annulus of the mitral valve, the straight, substantially rigid elongated body 157 or 157A will distort the natural configuration of the coronary sinus so that it will assume a substantially straight configuration. While this action induces the desired

- 38 -

valve remodeling, it can also induce a significant stress on the walls of the coronary sinus, particularly at the distal and proximal ends of the straight, substantially rigid elongated body 157 or 157A, where stress will be concentrated. To this end, the construction of the straight, substantially rigid elongated body 157 or 157A may be modified somewhat so as to better distribute this stress. More particularly, and looking next at Fig. 10, the distal and proximal ends of straight, substantially rigid elongated body 157 may include relatively flexible portions 175 to help better distribute the stress exerted on the walls of the coronary sinus. Additionally, and/or alternatively, any taper applied to the distal and proximal ends of straight, substantially rigid elongated body 157 may be elongated, e.g., such as shown at 178 in Fig. 11, so as to better distribute the stress imposed on the walls of the coronary sinus.

In the preceding discussion of system 100, push rod 109 is described as being inserted to the surgical site through the insertion cannula 106 and remaining

- 39 -

within insertion cannula 106 while at the surgical site  
and, when push rod 109 is to be removed, removing push  
rod 109 and then surgical cannula 106. However, if  
desired, once push rod 109 has been deployed at the  
5 surgical site, insertion cannula 106 may then be  
removed, leaving just push rod 109 at the surgical  
site. See, for example, Fig. 11A.

It is also possible to advance push rod 109  
directly to the surgical site without passing it  
10 through an insertion cannula; in this case push rod 109  
would be advanced on its own through the intervening  
vascular structure until it is deployed in coronary  
sinus 30.

Looking next at Fig. 12, there is shown a system  
15 181 which comprises another preferred embodiment of the  
present invention. More particularly, system 181  
generally comprises the guidewire 103, a straight,  
substantially rigid elongated body 184 and a push  
cannula 187.

20 Guidewire 103 is as previously described.

Straight, substantially rigid elongated body 184,  
which may have a variety of different lengths,

VIA-30

- 40 -

comprises a distal end 188 and a proximal end 190. A central lumen 193 extends between distal end 188 and proximal end 190. Central lumen 193 accommodates guidewire 103.

5           Push cannula 187 comprises a distal end 194 and a proximal end 196. A central lumen 199 extends between distal end 194 and proximal end 196. Central lumen 199 accommodates guidewire 103.

10           As a result of this construction, elongated body 184 and push cannula 187 may be mounted on guidewire 103, and push cannula 187 may be used to push elongated body 184 down guidewire 103. See Fig. 13.

System 181 may be used as follows to reduce mitral regurgitation.

15           First, distal end 115 of guidewire 103 is passed down jugular vein 18 (or the left subclavian vein 15) of a patient, down superior vena cava 9, through right atrium 24 of the heart, and into coronary sinus 30 (Fig. 14). It will be appreciated that as flexible  
20           guidewire 103 is passed down coronary sinus 30, the guidewire will tend to assume the natural curved shape of the coronary sinus, due to the flexible nature of

- 41 -

the guidewire. The guidewire's atraumatic spring tip 121 will help minimize damage to vascular structures as the guidewire is advanced into position.

5       Next, distal end 188 of straight, substantially rigid elongated body 184 is placed over proximal end 118 of guidewire 103 and passed a short distance down the guidewire. Then the distal end 194 of push cannula 187 is placed over proximal end 118 of guidewire 103, and then push cannula 187 is advanced down the  
10       guidewire. As push cannula 187 is advanced down the guidewire, its distal end 194 pushes the straight, substantially rigid elongated body 184 ahead of it. See Fig. 15.

15       As the straight, substantially rigid elongated body 184 is passed down the coronary sinus, it will force the coronary sinus to assume a straight configuration at the point where the straight, substantially rigid elongated body 184 currently resides. Push cannula 187 is pushed down guidewire as  
20       needed, until the straight, substantially rigid elongated body 184 is located adjacent to the posterior annulus of the mitral valve. See Fig. 16. As this

- 42 -

occurs, the presence of the straight, substantially rigid elongated body 184 in the coronary sinus will cause coronary sinus to assume a substantially straight configuration at this point, so that the posterior annulus of the mitral valve is forced anteriorly. This will cause the posterior mitral valve leaflet to also move anteriorly so as to improve leaflet coaptation and thereby reduce (or completely eliminate) mitral valve regurgitation. Using standard visualization means (e.g. echocardiography or fluoroscopy), the exact position of the straight, substantially rigid elongated body may be adjusted so as to reduce (or completely eliminate) regurgitation in the mitral valve.

If desired, the push cannula 187 may be provided with a releasably attachable interface (e.g., a grasper) so that it may releasably secure the proximal end 190 of the straight, substantially rigid elongated body 184. Such a feature will permit the straight, substantially rigid elongated body to be pulled backward within the coronary sinus, either for positioning or removal purposes.

- 43 -

Where elongated body 184 is to be left within the body for a substantial period of time, it is possible to leave the apparatus in the position shown in Fig. 16, i.e., with elongated body 184 fit over guidewire 103 and at the end of push cannula 187. Alternatively, 5 guidewire 103 and/or push cannula 187 may be removed, leaving just elongated body 184 deployed at the surgical site (Fig. 16A). To the extent that elongated body 184 may be left by itself at the surgical site, it 10 may be desirable to provide elongated body 184 with an eyelet or hook or other graspable feature G (Fig. 16B) such that a retriever R may thereafter be used to easily grapple and extract the elongated body 184 from the surgical site.

15 Elongated body 157 and/or elongated body 184 may have any of a variety of non-straight shapes along its length. For example, the elongated body may be wavy, spiraled, or curved along all or a portion of its length. By way of example, elongated body 157 and/or 20 184 may have a curved configuration so as to invert the natural curvature of the coronary sinus, i.e., so that it is bowed towards the anterior annulus. Or the

- 44 -

elongated body may have a compound shape along its length, e.g., it may have a sort of "w" shape, with the center of the "w" being directed towards the anterior annulus. See, for example, Fig. 17, which shows a push rod 109 having an elongated body 157 with a "w" type of shape; and see Fig. 18, which shows an elongated body 184 with a "w" type of shape. See also Figs. 19 and 20, which show a "w" shaped elongated body 184 being advanced down guidewire 103 (Fig. 19) to a position adjacent to mitral valve 36 (Fig. 20), whereby to reduce mitral regurgitation. Any of the aforementioned elongated body shapes, or other alternative shapes, may effect the anterior displacement of the posterior annulus that results in reduction of the mitral valve regurgitation.

It is preferable that use of the present invention not result in occlusion of coronary sinus 30. Thus, with system 100 shown in Fig. 3, delivery catheter 106 is preferably sized so as to have a diameter less than the diameter of coronary sinus 30, so that blood may flow about the perimeter of delivery catheter 106 when delivery catheter 106 is disposed in coronary sinus 30.

VIA-30

- 45 -

Alternatively, and/or additionally, and looking now at  
Figs. 21 and 22, delivery catheter 106 may be provided  
with one or more longitudinally-extending surface  
grooves SG so as to facilitate blood flow past the  
5 perimeter of delivery catheter 106. Similarly, with  
system 181 shown in Fig. 12, elongated body 184 is  
preferably sized so as to have a diameter less than the  
diameter of coronary sinus 30, so that blood may flow  
about the perimeter of elongated body 184 when  
10 elongated body 184 is disposed in coronary sinus 30.  
Alternatively, and/or additionally, and looking now at  
Figs. 23 and 24, elongated body 184 may be provided  
with one or more longitudinally-extending surface  
grooves SG so as to facilitate blood flow past the  
15 perimeter of elongated body 184.

In system 100 (Fig. 3) and in system 181 (Fig.  
12), the elongated bodies 157 and 184 are shown  
completely formed prior to their deployment in the  
patient. However, it is also possible to form  
20 elongated body 157 and/or elongated body 184 in situ  
from a plurality of smaller elements.

- 46 -

Thus, for example, in Figs. 25-27 there is shown an alternative form of push rod 109 for use with guidewire 103 and delivery catheter 106. More particularly, push rod 109 comprises flexible body 148 and a plurality of substantially rigid elongated elements 157A, 157B, 157C, etc. which collectively form the complete elongated body 157. Preferably the distalmost elongated element 157A is fixed to flexible body 148 while the remaining elongated elements 157B, 157C, 157D, etc. are free to slide on flexible body 148. In addition, elongated elements 157A, 157B, 157C, etc. preferably include connectors C for permitting one elongated element to be secured to a neighboring elongated body. The connectors C shown in Fig. 25 comprise male and female screw type connectors; however, other types of connectors may also be used.

By assembling the elongated body 157 in situ using a plurality of elongated elements 157A, 157B, 157C, etc., it is possible to create an elongated body 157 which is perfectly sized to the needs of the patient.

The push rod 109 shown in Figs. 25-27 may be used as follows. First, guidewire 103 is passed down to the

- 47 -

coronary sinus (Fig. 28). Then delivery catheter 106 is passed down guidewire 103 and into the coronary sinus (Figs. 28 and 29). Then the guidewire 103 is withdrawn from the surgical site and replaced by the push rod's flexible body 148 with elongated element 157A attached (Fig. 30). Next, a plurality of elongated elements 157B, 157C, 157D, etc. are slid down flexible body 148 (Fig. 31) and secured to elongated element 157A (and any preceding elongated element). As many elongated elements 157A, 157B, 157C, etc. are used as is necessary to effect the desired leaflet coaptation (Fig. 32).

In Figs. 32A-32C, there is shown another form of push rod 109. More particularly, with this form of the push rod, elongated body 157 is formed by a plurality of elongated elements 157A, 157B, 157C, etc. which collectively form the complete elongated body 157. Preferably the distalmost elongated element 157A is fixed to flexible body 148 while the remaining elongated elements 157A, 157B, 157C, etc. are free to slide on flexible body 148. With this version of the invention, elongated body 157 may be formed in situ by

- 48 -

moving elongated elements 157A, 157B, 157C, etc.  
distally, with distalmost elongated element 157A acting  
as a distal stop, and then keeping elongated elements  
157A, 157B, 157C, etc. biased distally with a holding  
5 mechanism, e.g., a crimp CR.

In Figs. 25-32, and in Figs. 32A-32C, elongated  
elements 157A, 157B, 157C, etc. are shown configured so  
as to form a substantially straight elongated body 157.  
However, if desired, elongated elements 157A, 157B,  
10 157C, etc. could have alternative configurations so as  
to form other body shapes. Thus, for example, in Fig.  
32D elongated elements 157A, 157B, 157C, etc. are shown  
forming a curved elongated body 157, and in Fig. 32E  
elongated elements 157A, 157B, 157C, etc. are shown  
15 forming a composite curved-and-straight elongated body  
157. It will be appreciated that still other shapes  
may be formed by elongated elements 157A, 157B, 157C,  
etc. In this respect, it will be appreciated that the  
shapes of elongated body 157 may be established either  
20 by (1) forming elongated elements 157A, 157B, 157C,  
etc. so that they have only one possible way of being  
assembled together, or (2) by forming elongated

- 49 -

elements 157A, 157B, 157C, etc. so that they have multiple ways of being assembled together. In this latter situation, one possible way to vary the final configuration of elongated body 157 is by individually rotating various ones of elongated elements 157A, 157B, 157C, etc., e.g., such as is shown in Figs. 32D and 32E.

As noted above, it is also possible to form the elongated body 184 of system 181 (Fig. 12) in situ from a plurality of smaller elements.

Thus, for example, in Figs. 33 and 34 there is shown an alternative form of elongated body 184 which comprises a plurality of substantially rigid elongated elements 184A, 184B, 184C, etc. which collectively form the complete elongated body 184. In addition, elongated elements 184A, 184B, 184C, etc. preferably include connectors C for permitting one elongated element to be secured to a neighboring elongated element. The connectors C shown in Fig. 25 comprise male and female screw type connectors; however, other types of connectors may also be used.

VIA-30

- 50 -

By assembling the elongated body 184 in situ using a plurality of elongated elements 184A, 184B, 184C, etc., it is possible to create an elongated body 184 which is perfectly sized to the needs of the patient.

5           The elongated body 184 shown in Figs. 33 and 34 may be used as follows. First, guidewire 103 is passed down coronary sinus 30 (Fig. 35). Then push cannula 187 is used to push a plurality of elongated elements 184A, 184B, 184C, etc. down guidewire 103 and into the  
10           coronary sinus (Figs. 36 and 37). As many elongated elements 184A, 184B, 184C, etc. are used as is necessary to effect the desired leaflet coaptation (Fig. 37).

          In Figs. 37A-37C, there is shown another form of  
15           elongated body 184. More particularly, with this form of elongated body, the elongated body 184 is formed by a plurality of elongated elements 184A, 184B, 184C, etc. which collectively form the complete elongated body 184. Preferably, all of the elongated elements  
20           184A, 184B, 184C, etc. are free to slide on guidewire 103. With this version of the invention, elongated body 184 may be formed in situ by moving elongated

- 51 -

elements 184A, 184B, 184C, etc. distally and then drawing them tightly together, e.g., such as by using a cinching system such as that shown in Fig. 37C and comprising a distal member DM and a crimp CR.

5           Again, in Figs. 33-37, and in Figs. 37A-37C, elongated element 184A, 184B, 184C, etc. are shown configured so as to form a substantially straight elongated body 184. However, if desired, elongated elements 184A, 184B, 184C, etc. could have alternative  
10           configurations so as to form other body shapes. Thus, for example, in Fig. 37D elongated elements 184A, 184B, 184C, etc. are shown forming a curved elongated body 184, and in Fig. 37E elongated elements 184A, 184B, 184C, etc. are shown forming a composite curved-and-  
15           straight elongated body 184. It will be appreciated that still other shapes may be formed by elongated elements 184A, 184B, 184C, etc. In this respect it will be appreciated that the shapes of elongated body 184 may be established either by (1) forming elongated  
20           elements 184A, 184B, 184C, etc. so that they have only one possible way of being assembled together, or (2) by forming elongated elements 184A, 184B, 184C, etc. so

- 52 -

that they have multiple ways of being assembled together. In this latter situation, one possible way to vary the final configuration of elongated body 184 is by individually rotating various ones of elongated elements 184A, 184B, 184C, etc., e.g., such as is shown in Figs. 37D and 37E.

Looking next at Figs. 37F-37I, there is shown another form of push rod 109 having an elongated body 157 formed by a plurality of elongated elements 157A, 157B, 157C, etc. Each of the elongated elements 157A, 157B, 157C, etc. is attached to flexible body 148 and is separated from adjacent elongated elements by a gap G. By orienting gaps G radially away from mitral valve 36 (Fig. 37H), push rod 109 will be able to curve as required so as to follow the natural curvature of the coronary sinus, e.g., during insertion of push rod 109 into coronary sinus 30. However, by rotating flexible body 148 about its axis so that gaps G are oriented 180 degrees opposite to that shown in Fig. 37H (i.e., as shown in Fig. 37I), gaps G will be closed and push rod 109 will be straightened, whereby to apply an

- 53 -

anteriorly-directed force to the posterior annulus of mitral valve 36 and reduce mitral regurgitation.

Looking next at Figs. 37J and 37K, there is shown another form of the invention. In this construction, an internal member IM has a plurality of slots SI and an external member EM has a plurality of slots SE. Internal member IM is concentrically received within external member EM. By orienting internal member IM and external member EM so that slots SI are aligned with slots SE (Fig. 37J), internal member IM and external member EM may be curved as required so as to follow the natural curvature of the coronary sinus, e.g. during insertion of the members into the coronary sinus. However, by orienting internal member IM and external member EM so that slots SI are oriented away from slots SE (Fig. 37K), internal member IM and external member EM will be straightened, whereby to apply an anteriorly-directed force to the posterior annulus of the mitral valve and reduce mitral regurgitation.

It is also possible to form elongated body 157 of push rod 109 (Fig. 3) with an inflatable construction.

VIA-30

- 54 -

More particularly, and looking next at Fig. 38, there is shown a push rod 109 having an inflatable elongated body 157 in the form of a balloon B. The push rod's flexible body 148 includes an inflation lumen L which  
5 communicates with the interior of balloon B, whereby fluid may be supplied to the interior of the balloon so as to inflate the balloon. The balloon B is constructed so that it has a flexible configuration when it is in a deflated condition and an elongated,  
10 straight configuration when it is in an inflated condition.

The push rod 109 of Fig. 38 may be used as follows. First, guidewire 103 is advanced into the coronary sinus 30 (Fig. 4). Then delivery cannula 106  
15 is advanced over guidewire 103 until the distal end of the delivery cannula is in coronary sinus 30 (Fig 5). Next, guidewire 103 is withdrawn (Fig. 6). Then push rod 109, with elongated body 157 in a deflated condition, is advanced along the interior of delivery  
20 cannula 106 so that balloon B is adjacent to the mitral valve (Fig. 39). Then balloon B is inflated, using inflation lumen L, so that elongated body assumes its

- 55 -

elongated, straightening configuration (Fig. 40). As this occurs, the posterior annulus of the mitral valve is compressed anteriorly, so as to reduce mitral regurgitation.

5           It is also possible to form an inflatable elongated body 157 of push rod 109 with other configurations. By way of example, it is possible to form an inflatable body 157 with a piston-type configuration, whereby the body may be elongated or  
10           shortened as desired. More particularly, and looking now at Figs. 41 and 42, inflatable body 157 may comprise a distal portion 157' and a proximal portion 157'', with the distal and proximal portions being in a sliding, piston-like relationship. As a result, fluid  
15           may be supplied to the combined interiors of the distal and proximal portions, so as to force the two elements apart relative to one another. In use, the push rod 109 of Figs. 41 and 42 is positioned in its "compressed" state (Fig. 41), passed down the interior  
20           of delivery cannula 106 until inflatable elongated body 157 is positioned adjacent to the mitral valve, and then inflated (using inflation lumen L) into its

VIA-30

- 56 -

"expanded" state (Fig. 42). As this occurs, the naturally curved coronary sinus is straightened, thereby pushing the posterior annulus of the mitral valve anteriorly, whereby to reduce mitral regurgitation.

In addition to the foregoing, it should also be appreciated that with respect to push rod 109, the flexible body 148 may comprise an electrical lead for an implantable bi-ventricular pacing device and/or an electrical lead for an implantable cardio defibrillator device, etc. In this case, the distal end of flexible body 148 would be elongated somewhat and would not reside within the coronary sinus; rather, it would be positioned within the tissue which is to receive the electrical stimulus while elongated body 157 is positioned adjacent to the mitral valve. Such a construction would allow the bi-ventricular pacing device and/or the implantable cardio defibrillator device to work in conjunction with elongated body 157 to reduce mitral regurgitation.

It should also be appreciated that the function of hydraulic energy employed to enlarge inflatable body

- 57 -

157 may be substituted by a mechanical energy transformer such as a lead screw mechanism or an electromechanical solenoid.

5 In a corresponding fashion, the guidewire 103 over which elongated body 184 is deployed may also be in the form of an electrical lead for an implantable bi-ventricular pacing device and/or an electrical lead for an implantable cardio defibrillator device, etc. Again, in this case the distal end of the wire will be  
10 positioned within the tissue which is to receive the electrical stimulus while elongated body 184 is positioned adjacent to the mitral valve. Such a construction would allow the implantable bi-ventricular pacing device and/or the implantable  
15 cardio defibrillator device to work in conjunction with elongated body 157 to reduce mitral regurgitation.

Looking next at Figs. 43 and 44, there is shown yet another form of the present invention. In this form of the invention, there is provided an elongated  
20 shape memory alloy body SMA which is configured to be substantially flexible at a temperature  $T_1$  and substantially rigid and in a straight configuration at

- 58 -

another temperature  $T_2$ , where temperature  $T_2$  is normal body temperature. In this situation, body SMA is brought to temperature  $T_1$ , so that it may be inserted more easily into the natural curvature of the coronary sinus, e.g., during insertion of body SMA into the coronary sinus (Fig. 43). However, when body SMA thereafter transitions to temperature  $T_2$ , body SMA will assume its straight configuration (Fig. 44), whereby to apply an anteriorly-directed force to the posterior annulus of the mitral valve and reduce mitral regurgitation. It will be appreciated that the configuration of body SMA may be other than straight (i.e., "w" shape, etc.) to best displace the posterior annulus anteriorly.

In other alternative embodiments, the elongated body may be flexible along at least a portion of its length. Regional flexibility and regional stiffness may allow for straightening of select locations of the coronary sinus and corresponding locations of the posterior mitral annulus. This can cause regions of the mitral annulus to move anteriorly, thus causing regional improvements in leaflet coaptation. In

- 59 -

addition, the elongated body may be formed by two end segments connected together by a filament: by anchoring the two end segments relative to the anatomy and pulling the filament taught, the naturally curved wall of the coronary sinus can be straightened, whereby to move the posterior mitral annulus anteriorly and thereby reduce mitral regurgitation.

In Figs. 45-47, there is illustrated an alternative method for reducing mitral regurgitation, wherein deforming matter is deployed into either the mitral valve annulus 33 adjacent the posterior leaflet 39 or the tissue 200 adjacent the annulus 33 near the posterior leaflet.

Turning to Fig. 45, it will be seen that in accordance with the alternative method, an injection needle 202 is channeled through a delivery catheter 106 and is inserted in the tissue 200 between the coronary sinus 30 and the mitral valve annulus 33. Alternatively, the injection needle 202 can be inserted into the annulus 33 adjacent the posterior leaflet.

The injection needle 202 is retracted and as it is retracted (Fig. 46) deforming matter 204 is expelled

VIA-30

- 60 -

from the needle (Fig. 46). The deforming matter 204 causes a conformational change in the annulus 33 of the mitral valve 36 (Fig. 47), to move the posterior leaflet 39 towards the anterior leaflet 42, to increase mitral valve posterior leaflet coaptation with the anterior leaflet, reducing or eliminating the gap 45 therebetween.

Deployment of the deforming matter 204 into the mitral valve annulus 33 causes displacement of the annulus adjacent the posterior leaflet, to cause displacement of the posterior leaflet 39 toward the anterior leaflet 42.

Similarly, deployment of the deforming matter 204 into the tissue 200 causes a conformational change in the mitral valve annulus, which displaces the mitral valve annulus adjacent the posterior leaflet, and thereby the posterior leaflet, toward the mitral valve anterior leaflet, to reduce or close the gap 45 between the leaflets 39, 42 (Fig. 47).

The deforming matter may be in the nature of a device or devices for mechanically effecting a movement of the posterior leaflet, such as one or more

VIA-30

- 61 -

solid bodies or rigid bodies, which may in turn take the form of an articulating assembly of bodies, a monofilament, a bar, or solid pellets, or powder, or the like. Alternatively, the deforming matter may be in the form of a stent or a sponge, or of a fluid nature, such as a gel, a saline solution, or a gas, or may be in the form of capsules containing such fluids and these capsules may or may not permit such fluids to exit the capsules over time. The deforming matter may be in the form of a hydrogel which absorbs fluid from the body in which it is deployed.

The deforming matter may be a scarring substance which changes the conformation of the mitral valve annulus 33 and/or tissue 200, to cause contraction of the annulus 33 to effect the desired closure of the gap 45. As in the case of the aforementioned deforming matter, the scarring substance can be injected directly into the annulus 33 adjacent the posterior leaflet 39, or into the tissue 200 proximate the posterior leaflet. Scarring may also be induced through the application of electrical energy, in which case needle 202 might be replaced by one or more electrodes.

VIA-30

- 62 -

In another alternative embodiment, the deforming matter comprises a balloon 206 illustrated in Figs. 48-51. As shown in Fig. 48, the injection guidewire/needle 202 with the deflated balloon 206 therearound, may be guided by the delivery catheter 106 into the coronary sinus 30 and thence into the tissue 200 or the annulus 33, the former being illustrated in Fig. 48. The deflated balloon 206 is passed through the delivery catheter 106, along with the guidewire/needle 202, such that the deflated balloon resides in part in the tissue 200 and in part in the coronary sinus 30.

The balloon 206 is then inflated through the guidewire/needle as the guidewire/needle 202 is withdrawn (Fig. 50), causing the posterior leaflet 39 to be moved toward the anterior leaflet 42, to reduce or close the gap 45. The balloon is inflated to a volume and stiffness to effect the desired conformational change to the mitral valve annulus 33, and thereby the posterior leaflet 39. The delivery catheter 106 is then withdrawn, leaving the inflated balloon 206 in place.

VIA-30

- 63 -

It should be appreciated that the present invention may be used to alter the shape of other cardiac tissues, including but not limited to the left ventricle, for other uses, including the treatment of cardiac dysfunction.

It is to be understood that the present invention is by no means limited to the particular constructions herein disclosed and/or shown in the drawings, but also comprises any modifications or equivalents within the scope of the claims.

- 64 -

What Is Claimed Is:

1. A method for reducing mitral regurgitation,  
the method comprising deploying deforming matter into a  
5 selected one of (i) a mitral valve annulus adjacent a  
posterior leaflet and (ii) tissue adjacent the mitral  
valve annulus proximate the posterior leaflet, to cause  
a conformational change in the annulus, and thereby a  
conformational change in the posterior leaflet, to  
10 increase mitral valve leaflet coaptation.

2. The method in accordance with claim 1 wherein  
the deforming matter is deployed into the mitral valve  
annulus in such a manner as to displace the posterior  
15 leaflet toward a mitral valve anterior leaflet.

3. The method in accordance with claim 1 wherein  
the deforming matter is deployed into the tissue  
adjacent the mitral valve annulus adjacent the  
20 posterior leaflet to cause the conformational change in  
the mitral valve annulus which displaces the mitral  
valve annulus adjacent the posterior leaflet, and

VIA-30

- 65 -

thereby the posterior leaflet, toward a mitral valve  
anterior leaflet.

4. The method in accordance with claim 1 wherein  
5 the deforming matter comprises a device which is at  
least one of (i) solid and (ii) substantially rigid.

5. The method in accordance with claim 4 wherein  
the device comprises a selected one of (i) a stent,  
10 (ii) an articulating structure, (iii) a monofilament,  
(iv) a bar, and (v) solid pellets.

6. The method in accordance with claim 1 wherein  
the deforming matter comprises a substance which  
15 occupies a volume of the selected one of (i) the mitral  
valve annulus, and (ii) the tissue adjacent thereto, to  
cause the conformational change to the annulus and  
thereby the posterior leaflet.

20 7. The method in accordance with claim 6 wherein  
the deforming substance comprises at least one of a  
gel, a saline solution, a sponge, a powder, and a gas.

VIA-30

- 66 -

5           8.    The method in accordance with claim 6 wherein  
the deforming substance comprises capsules containing  
at least one of a gel, a saline solution, a powder and  
a gas.

          9.    The method in accordance with claim 6 wherein  
the deforming matter comprises a hydrogel.

10           10. The method in accordance with claim 1 wherein  
the deforming matter comprises a scarring substance  
which causes contraction of the mitral valve annulus to  
effect the conformational change thereof.

15           11. The method in accordance with claim 10  
wherein deploying the scarring substance comprises  
injecting the scarring substance directly into the  
selected one of the mitral valve annulus and the tissue  
adjacent thereto.

20           12. The method in accordance with claim 1 wherein  
the deforming matter comprises at least one balloon.

VIA-30

- 67 -

13. The method in accordance with claim 12  
wherein a needle is used to puncture a coronary sinus  
proximate the mitral valve posterior leaflet and insert  
5 the at least one balloon into the selected one of the  
mitral annulus and the tissue adjacent thereto.

14. The method in accordance with claim 13  
wherein the at least one balloon is elongated and is  
10 inflated by the needle as the needle is withdrawn.

15. The method in accordance with claim 14  
wherein the at least one balloon is inflated to a  
volume and stiffness to effect a desired conformational  
15 change to the mitral valve annulus and thereby the  
posterior leaflet.

16. A method for reducing mitral regurgitation,  
the method comprising deploying deforming matter into a  
20 at least one of (i) a mitral valve annulus and (ii)  
tissue adjacent the mitral valve annulus, to cause a  
conformational change in the annulus, and thereby a

VIA-30

- 68 -

posterior leaflet, to increase mitral valve leaflet coaptation.

17. An assembly for reducing mitral  
5 regurgitation, the assembly comprising:  
a delivery catheter adapted for insertion into a coronary sinus;

a needle for movement through said delivery  
catheter and adapted to penetrate the coronary sinus  
10 and enter tissue between the coronary sinus and a mitral valve annulus adjacent a posterior leaflet, and adapted to enter the mitral valve annulus, and

deforming matter adapted to be carried by the  
needle and deployed in at least one of the tissue and  
15 the mitral valve annulus.

18. The assembly in accordance with claim 17  
wherein said deforming matter comprises at least one of  
a mechanical structure, a fluid, a gel, a hydrogel, a  
powder, pellets, a scarring substance, a balloon, and a  
20 capsule containing a selected one of the fluid, the gel, the hydrogel, the powder, and the scarring substance.
